Description			
If I have a custom variable list of the values A, B and C, I'd like to be able to bulk edit a list of tickets and add B to all the issues.			
So, I'd start with the following issues with the following values in the custom variable:			
issue id	A	B	C
143	true	false	true
235	false	true	true
981	false	false	true

Then after bulk editing to select B I'd have:

issue id	A	B	C
143	true	true	true
235	false	true	true
981	false	true	true

Then I could bulk edit A to be false and get:

issue id	A	B	C
143	false	true	true
235	false	true	true
981	false	true	true

This will allow me to label tickets as being for different parts of our project. So issue 143 is not about search, but is about price and images.

Then I can get a list of all the tickets relating to images and set images to true in the list.

I could work around this by making a boolean custom variable for each option on the list but it would end up being quite messy.
